

Abstract of the Disclosure

A hook device includes a case member for supporting a hook main portion to be rotatable between a store position and a use position; a stopping portion attached to the case member for regulating the hook main portion at the use position with a predetermined opening angle; and an engaging portion provided to the hook main portion through an elastic member for engaging the stopping portion. The elastic member elastically deforms in a direction that the stopping portion engages the engaging portion when a load is applied to the hook main portion in a direction that the hook main portion opens.
